

Well-founded models in proofs of termination

Salvador Lucas

DSIC, Universitat Politècnica de València (UPV)

<http://slucas.webs.upv.es/>

16th INTERNATIONAL WORKSHOP ON TERMINATION (WST 2018)
OXFORD, UNITED KINGDOM

Main goal

Understanding, *analyzing*, and *automatically verifying* the termination behavior of declarative programs (e.g., Maude)

```
fmod PALINDROME is
  protecting QID .
  sorts List Pal .
  subsorts Qid < Pal < List .
  op nil : -> Pal .
  op __ : List List -> List .
  var I : Qid .
  var P : Pal .
  mb I P I : Pal .
endfm

fmod PROGRAM is
  sort S .
  ops a b : -> [S] .
  ceq a = b if a : S .
endfm
```

Challenging!

PALINDROME is (obviously?) *terminating*. PROGRAM is *not* (why?).

A theory \mathcal{S} in a logic \mathcal{L} is called *operationally terminating* if no infinite *well-formed* proof tree for \mathcal{S} exists [LMM05].

Infinite branches are captured by using *proof jumps* $A \uparrow B_1, \dots, B_{n-1}, B_n$ associated to the *inference rules* $\frac{B_1 \dots B_n \dots B_p}{A}$ of \mathcal{S} [LM14].

Use of logical models and well-founded relations

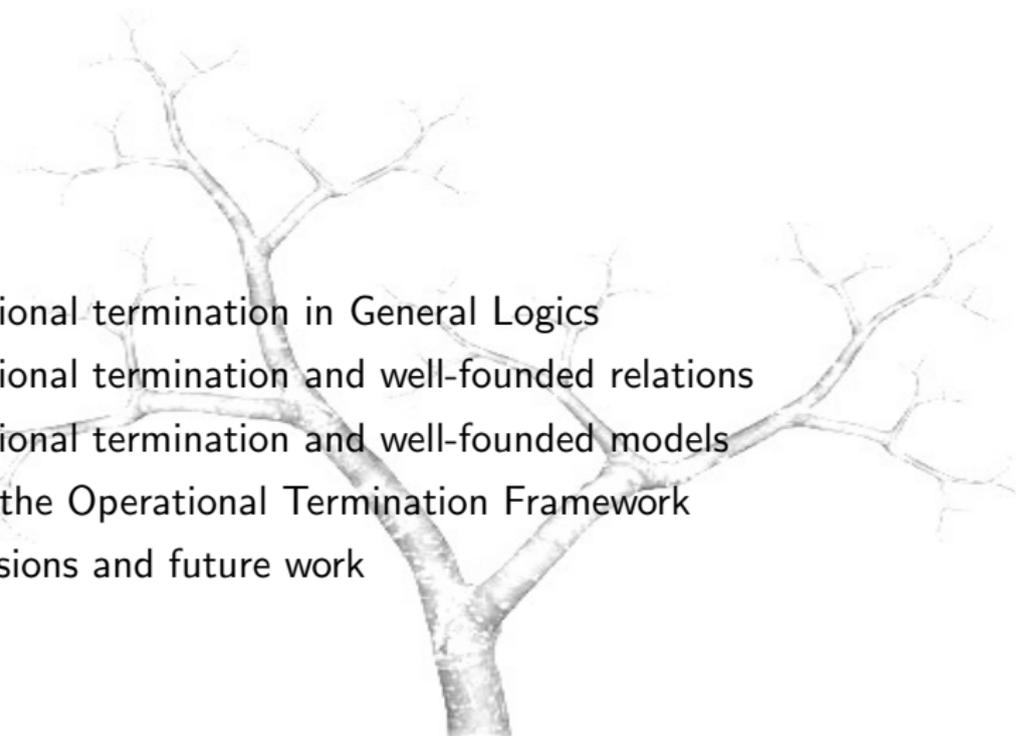

Provability of goals $\sigma(B_1), \dots, \sigma(B_{n-1})$ captured by *logical models* when needed

The *head* A and the *hook* B_n of proof jumps indicate where *well-founded* relations \sqsupset are required to prove termination: $\sigma(A) \sqsupset \sigma(B_n)$

Termination proofs = Logical models + Well-founded relations

Outline

- 
- 1 Operational termination in General Logics
 - 2 Operational termination and well-founded relations
 - 3 Operational termination and well-founded models
 - 4 Use in the Operational Termination Framework
 - 5 Conclusions and future work

Operational termination in General Logics

A logical approach to declarative programming [Mes87]

- ① *Declarative programs* \mathcal{S} are *theories* of a given *logic* \mathcal{L} .
- ② *Computations* with \mathcal{S} are implemented as *deductions* in \mathcal{L} .
- ③ *Deductions* proceed according to the *Inference System* $\mathcal{I}(\mathcal{L})$ of \mathcal{L} .

Definition (Proof jumps of a theory \mathcal{S} [LM14])

$$\mathcal{J}_{\mathcal{S}} = \{(A \uparrow \vec{B}_i) \mid \frac{\vec{B}_n}{A} \in \mathcal{I}(\mathcal{S}), 1 \leq i \leq n\}$$

The specialization of the inference system for CS-MRTs [DLM⁺08] yields $\mathcal{I}(\text{PALINDROME})$ with *16 rules*.

Subject Reduction rules concern the dependency of sorts with *rewritings*

$$(SR)_Q \frac{x \rightarrow y \quad y : \text{Qid}}{x : \text{Qid}} \quad (SR)_P \frac{x \rightarrow y \quad y : \text{Pal}}{x : \text{Pal}} \quad (SR)_L \frac{x \rightarrow y \quad y : \text{List}}{x : \text{List}}$$

Membership rules describe the association of sorts to expressions by means of conditional memberships in the program.

$$(M1)_{Q < P} \frac{x :: \text{Qid}}{x :: \text{Pal}} \quad (M1)_{P < L} \frac{x :: \text{Pal}}{x :: \text{List}} \quad (M1)_Q^c \frac{}{c :: \text{Qid}} \text{ for } c \text{ of sort Qid}$$

$$(M1)_{\text{nil}} \frac{}{\text{nil} :: \text{Pal}} \quad (M1)_{-} \frac{x :: \text{List} \quad y :: \text{List}}{x \ y :: \text{List}} \quad (M1)_{\text{mbP}} \frac{I :: \text{Qid} \quad P :: \text{Pal}}{IPI :: \text{Pal}}$$

$$(M2)_Q \frac{x :: \text{Qid}}{x : \text{Qid}} \quad (M2)_P \frac{x :: \text{Pal}}{x : \text{Pal}} \quad (M2)_L \frac{x :: \text{List}}{x : \text{List}}$$

Reflexivity and *transitivity* rules for the many step rewrite relations.

$$(Rf)_L \frac{}{x \rightarrow^* x} \quad (T)_L \frac{x \rightarrow y \quad y \rightarrow^* z}{x \rightarrow^* z}$$

The *congruence rules* propagate one-step reductions.

$$(C)_{-,,1} \frac{x \rightarrow y}{x \ z \rightarrow y \ z} \quad (C)_{-,,2} \frac{x \rightarrow y}{z \ x \rightarrow z \ y}$$

Given $\frac{B_1 \cdots B_n}{A}$ with label ρ and $1 \leq i \leq n$, $[\rho]^i$ is the i -th proof jump
 $A \uparrow B_1, \dots, B_i$ obtained from ρ .

Example

The proof jumps obtained from the inference rule

$$(M1)_{\text{mbP}} \quad \frac{I :: \text{Qid} \quad P :: \text{Pa1}}{IPI :: \text{Pa1}}$$

are the following:

$$\begin{aligned} [(M1)_{\text{mbP}}]^1 &: IPI :: \text{Pa1} \uparrow I :: \text{Qid} \\ [(M1)_{\text{mbP}}]^2 &: IPI :: \text{Pa1} \uparrow I :: \text{Qid}, P :: \text{Pa1} \end{aligned}$$

Operational termination and well-founded relations

Theorem (OT and well-founded relations)

A theory \mathcal{S} is operationally terminating iff there is a *well-founded relation* \sqsupset (on *formulas*) such that, for all $A \uparrow \vec{B}_n \in \mathcal{J}_S$,

for all σ , if $\mathcal{S} \vdash \sigma(B_i)$ for all i , $1 \leq i < n$, then $\sigma(A) \sqsupset \sigma(B_n)$ (1)

Proof keys:

- *if part* (by contradiction): an infinite well-formed proof tree is represented by an infinite sequence of (instances of) proof jumps which (by hypothesis) lead to an infinite sequence of comparisons with \sqsupset and then to a contradiction.
- *only if part*: by operational termination, a well-founded *proof progress* relation on formulas $\uparrow\uparrow$ is defined by considering all possible well-formed proof trees and the forks we can follow to go up on it. By construction, $\uparrow\uparrow$ can be taken as \sqsupset to satisfy (1).

Theorem (OT and well-founded relations)

A theory \mathcal{S} is operationally terminating iff there is a *well-founded relation* \sqsupset (on *formulas*) such that, for all $A \uparrow \vec{B}_n \in \mathcal{J}_{\mathcal{S}}$,

for all σ , if $\mathcal{S} \vdash \sigma(B_i)$ for all i , $1 \leq i < n$, then $\sigma(A) \sqsupset \sigma(B_n)$

How to use this result to *prove* OT? Problems:

- ① infinitely many substitutions σ
- ② provability statements $\mathcal{S} \vdash \sigma(B_i)$
- ③ symbol \sqsupset does *not* belong to the language of \mathcal{S}

Idea

Encode as a *first-order satisfiability* problem

Operational termination and well-founded models

In the following result, \mathcal{S} is a **first-order theory**, and

- $\bar{\mathcal{S}}$ is obtained from $\mathcal{I}(\mathcal{S})$ by interpreting inference rules $\frac{B_1 \dots B_n}{A}$ as **first-order sentences** $(\forall \vec{x}) B_1 \wedge \dots \wedge B_n \Rightarrow A$.
- \downarrow is a **transformation** $P(t_1, \dots, t_n)^\downarrow = f_P(t_1, \dots, t_n)$ from **atoms** $P(t_1, \dots, t_n)$ into **terms** $f_P(t_1, \dots, t_n)$ of a **new sort** s_τ , where $f_P : w \rightarrow s_\tau$ are new **function symbols** for each **predicate** $P : w$.
- $\pi_\sqsupset : s_\tau s_\tau$ is a **new** binary (infix) **predicate** accepting terms of sort s_τ .

Theorem (OT and well-founded models)

A theory \mathcal{S} is **operationally terminating** if and only if there is an **interpretation** \mathcal{A} with no empty domain such that

$$\mathcal{A} \models \bar{\mathcal{S}} \cup \{B_1 \wedge \dots \wedge B_{n-1} \Rightarrow A^\downarrow \pi_\sqsupset B_n^\downarrow \mid A \uparrow \vec{B}_n \in \mathcal{I}_\mathcal{S}\}$$

and $\pi_\sqsupset^{\mathcal{A}}$ is **well-founded** on \mathcal{A}_{s_τ} .

Example (Operational termination of PALINDROME)

We use **S** instead of **Qid** to make some symbols (**a** and **b**) *available* for sequencing. With AGES [GLR16], a model \mathcal{A} is obtained [LG18]:

$$\mathcal{A}_S = \mathcal{A}_{\text{Pal}} = \mathbb{N} - \{0\} \quad \mathcal{A}_{\text{List}} = \mathbb{N} \quad \mathcal{A}_{s_\tau} = \mathbb{N} \cup \{-1\}$$

Function symbols are interpreted as follows:

$$\begin{array}{lll} a^{\mathcal{A}} = b^{\mathcal{A}} = 1 & \text{nil}^{\mathcal{A}} = 1 & x_ _^{\mathcal{A}} y = x + y + 1 \\ f_{_ : S}^{\mathcal{A}}(x) = 3x & f_{_ : \text{Pal}}^{\mathcal{A}}(x) = 2x + 1 & f_{_ : \text{List}}^{\mathcal{A}}(x) = 2x + 2 \\ f_{_ : S}^{\mathcal{A}}(x) = -1 & f_{_ : \text{Pal}}^{\mathcal{A}}(x) = 2x & f_{_ : \text{List}}^{\mathcal{A}}(x) = 2x + 1 \\ f_{\rightarrow}^{\mathcal{A}}(x, y) = 2x - 1 & f_{\rightarrow^*}^{\mathcal{A}}(x, y) = 4x + y + 1 & \end{array}$$

Finally, predicates are interpreted as follows:

$$\begin{array}{lll} _ : S^{\mathcal{A}}(x) \Leftrightarrow \text{true} & _ : \text{Pal}^{\mathcal{A}}(x) \Leftrightarrow \text{true} & _ : \text{List}^{\mathcal{A}}(x) \Leftrightarrow \text{true} \\ _ : S^{\mathcal{A}}(x) \Leftrightarrow x \geq 1 & _ : \text{Pal}^{\mathcal{A}}(x) \Leftrightarrow x \geq 1 & _ : \text{List}^{\mathcal{A}}(x) \Leftrightarrow x \geq 1 \\ x \rightarrow^{\mathcal{A}} y \Leftrightarrow x > y & x(\rightarrow^*)^{\mathcal{A}} y \Leftrightarrow \text{true} & x \pi_{\square}^{\mathcal{A}} y \Leftrightarrow x > y \end{array}$$

Use in the Operational Termination Framework

A *removal pair* (\succsim, \sqsupset) , consists of binary relations \succsim and \sqsupset on *formulas* such that \sqsupset is *well-founded* and $\succsim \circ \sqsupset \subseteq \sqsupset$ (or $\sqsupset \circ \succsim \subseteq \sqsupset$).

Definition (Removal pair processor [LM14])

$P_{RP}(\mathcal{S}, \mathcal{J}) = \{(\mathcal{S}, \mathcal{J} - \{\psi\})\}$ iff

- 1 for all $C \uparrow \vec{D}_m \in \mathcal{J} - \{\psi\}$ and substitutions σ , if $\mathcal{S} \vdash \sigma(D_i)$ for all $1 \leq i < m$, then $\sigma(C) \succsim \sigma(D_m)$ or $\sigma(C) \sqsupset \sigma(D_m)$, and
- 2 for all substitutions σ , if $\mathcal{S} \vdash \sigma(B_i)$ for all $1 \leq i < n$, then $\sigma(A) \sqsupset \sigma(B_n)$.

Definition (Semantic version of P_{RP} [Luc16])

$P_{RP}(\mathcal{S}, \mathcal{J}) = \{(\mathcal{S}, \mathcal{J} - \{\psi\})\}$ if

- 1 $\mathcal{A} \models \bar{\mathcal{S}}$,
- 2 if $\mathcal{J} - \{\psi\} \neq \emptyset$, then $\mathcal{A} \models x \pi_{\succeq} y \wedge y \pi_{\sqsupset} z \Rightarrow x \pi_{\sqsupset} z$,
- 3 for each $C \uparrow \vec{D}_m \in \mathcal{J} - \{\psi\}$, there is $\pi_{\boxtimes} \in \{\pi_{\succeq}, \pi_{\sqsupset}\}$ such that $\mathcal{A} \models \bigwedge_{i=1}^{m-1} D_i \Rightarrow C \downarrow \pi_{\boxtimes} D_m \downarrow$, and
- 4 $\pi_{\sqsupset}^{\mathcal{A}}$ is well-founded and $\mathcal{A} \models \bigwedge_{i=1}^{n-1} B_i \Rightarrow A \downarrow \pi_{\sqsupset} B_n \downarrow$

Example (Use of the semantic version of P_{RP})

Consider the CTRS $\mathcal{R} = \{a \rightarrow b, f(a) \rightarrow b, g(x) \rightarrow g(a) \Leftarrow f(x) \rightarrow x\}$ in [GA01, page 46], where $\mathcal{I}(\mathcal{R})$ is:

$$\begin{array}{ll}
 (Rf) \frac{}{x \rightarrow^* x} & (T) \frac{x \rightarrow y \quad y \rightarrow^* z}{x \rightarrow^* z} \\
 (RI)_1 \frac{}{a \rightarrow b} & (RI)_2 \frac{}{f(a) \rightarrow b} \\
 & (C)_{f,1} \frac{x \rightarrow y}{f(x) \rightarrow f(y)} \quad (C)_{g,1} \frac{x \rightarrow y}{g(x) \rightarrow g(y)} \\
 & (RI)_3 \frac{f(x) \rightarrow^* x}{g(x) \rightarrow g(a)}
 \end{array}$$

We can **remove** $[(T)]^2$ from the **initial OT problem** $\tau_I = (\mathcal{R}, \mathcal{J}_{\mathcal{R}})$. A model \mathcal{A} with **finite** domain $\mathcal{A} = \{0, 1, 2, 3\}$ is found with **Mace4** [McC10]:

$$\begin{array}{lll}
 a^{\mathcal{A}} = 0 & b^{\mathcal{A}} = 1 & f^{\mathcal{A}}(x) = (x + 2) \bmod 4 \\
 g^{\mathcal{A}}(x) = x \bmod 2 & f_{\rightarrow}^{\mathcal{A}}(x, y) = x \bmod 2 & f_{\rightarrow^*}^{\mathcal{A}}(x, y) = x \bmod 2 \\
 \rightarrow^{\mathcal{A}} = \{(0, 1), (0, 3), (2, 1), (2, 3)\} & (\rightarrow^*)^{\mathcal{A}} = \{(x, x) \mid x \in \mathcal{A}\} \cup \rightarrow^{\mathcal{A}} & \\
 \pi_{\sqsupset}^{\mathcal{A}} = \{(0, 1)\} & (\pi_{\succeq})^{\mathcal{A}} = \{(0, 0), (1, 1)\} & \\
 (\pi_{\sqsupset}^+)^{\mathcal{A}} = \{(0, 1)\} & &
 \end{array}$$

Successive applications of P_{RP} prove **operational termination** of \mathcal{R} .

Conclusions and future work

Our approach [LM14]:

- 1 *Declarative programs* P are *theories* of a given *logic* \mathcal{L}
- 2 *Operational termination* characterizes the *termination behavior* of P as the absence of *infinite proof trees* for P (using $\mathcal{I}(\mathcal{L})$)
- 3 *Proof jumps* capture infinite proof trees in computations.
- 4 The *OT Framework* provides a practical approach to prove or disprove finiteness of OT problems

Termination proofs via logical models and well-founded relations

Logic provides the expressive framework to describe the *language semantics* which is captured by *logical models* when needed

Proof jumps indicate where *well-founded* relations are required to prove termination.

Termination proofs = Logical models + Well-founded relations

In the early literature on termination of (variants of) *Term Rewriting Systems*, well-founded orderings have been pervasive...

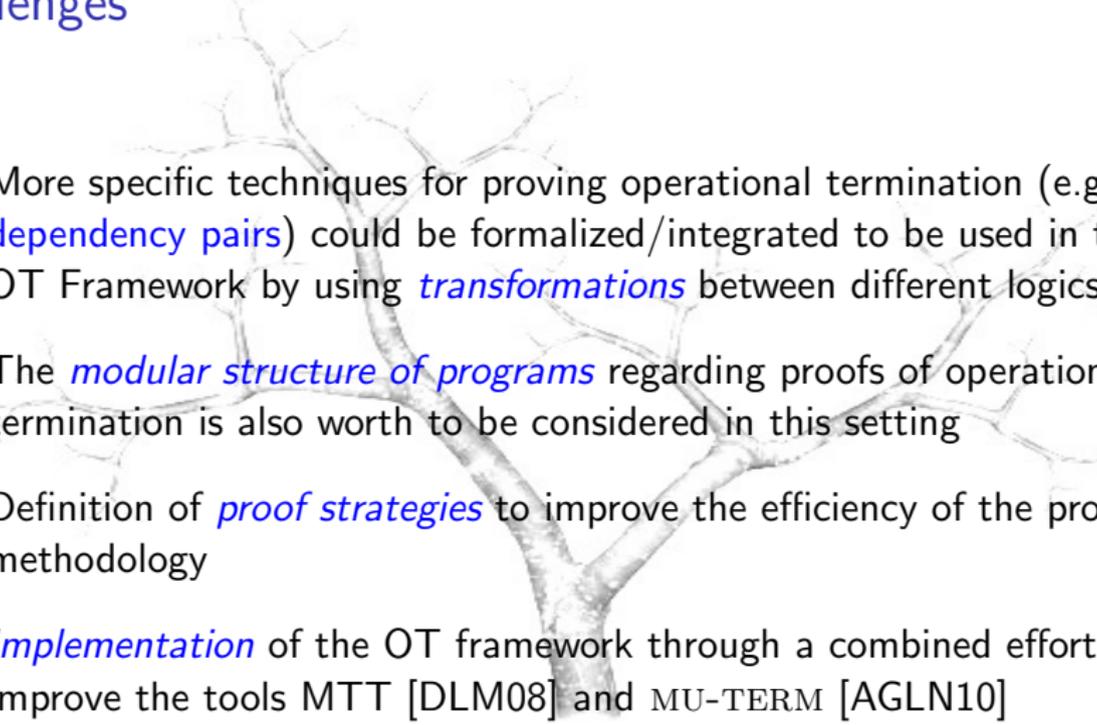

...often as a *particular* requirement *together with* those having to do with the specific *variant* at stake:

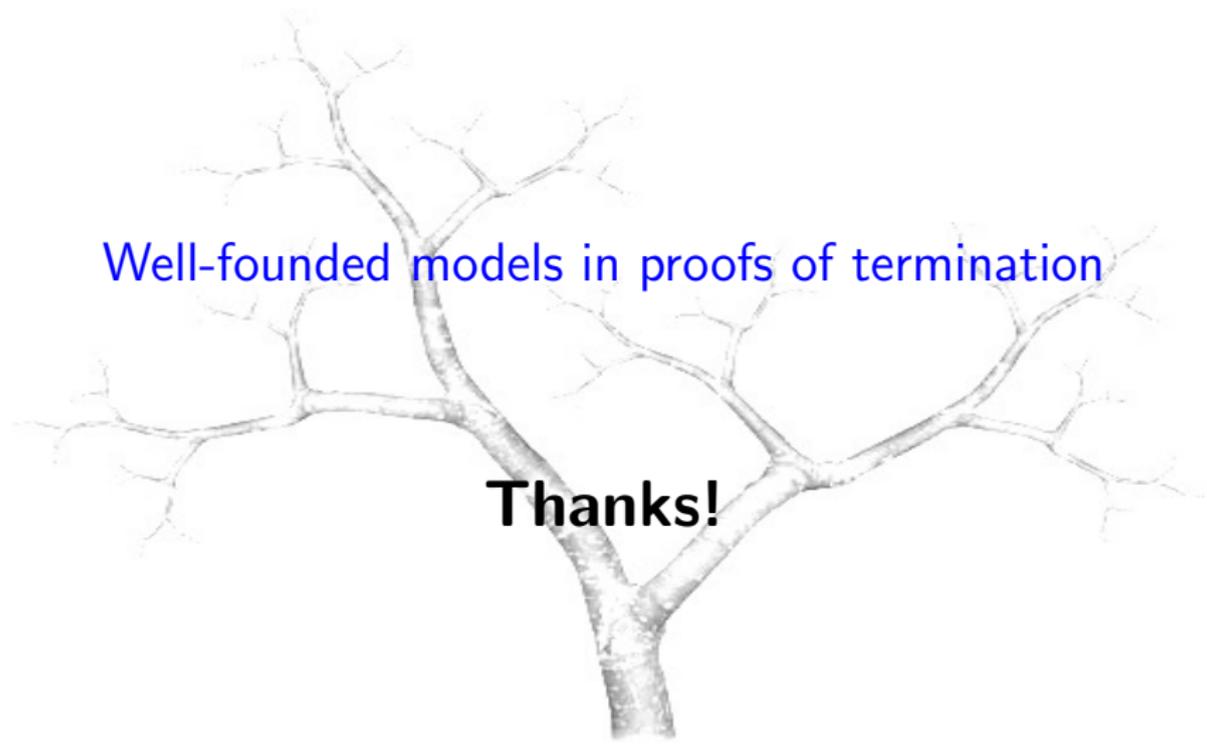

Variant	Name	Specific requirements
TRS	reduction ordering	monotonicity, stability
AC-TRS	AC-reduction ordering	compatibility with AC axioms
CS-TRS	μ -reduction ordering	μ -monotonicity, stability
CTRS	quasi-decreasingness	subterm property
CRMS	reductivity	monotonicity, stability, use of \triangleright
⋮	⋮	⋮

A unified treatment of rewriting-based systems

All these specific requirements are *naturally* obtained from the *logical structure* of the programming language semantics.

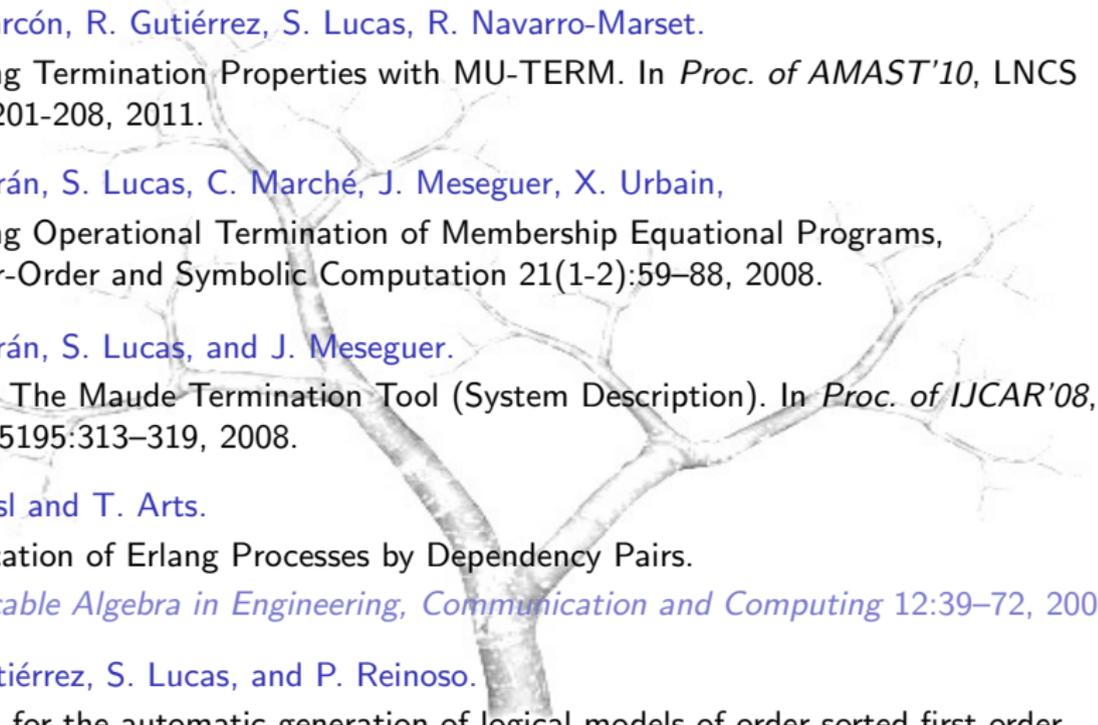

Challenges

- 
- ① More specific techniques for proving operational termination (e.g., *dependency pairs*) could be formalized/integrated to be used in the OT Framework by using *transformations* between different logics
 - ② The *modular structure of programs* regarding proofs of operational termination is also worth to be considered in this setting
 - ③ Definition of *proof strategies* to improve the efficiency of the proof methodology
 - ④ *Implementation* of the OT framework through a combined effort to improve the tools MTT [DLM08] and MU-TERM [AGLN10]
