Figure 1. **Text-to-Image Generation Results by FlowTok.** FlowTok projects both text and images into a unified, compact 1D latent space, enabling direct flow matching between 1D tokens and facilitating the efficient generation of diverse, high-fidelity images.

## Abstract

Bridging different modalities lies at the heart of cross-modality generation. While conventional approaches treat the text modality as a conditioning signal that gradually guides the denoising process from Gaussian noise to the target image modality, we explore a much simpler paradigm—directly evolving between text and image modalities through flow matching. This requires projecting both modalities into a shared latent space, which poses a significant challenge due to their inherently different representations: text is highly semantic and encoded as 1D tokens, whereas images are spatially redundant and represented as

2D latent embeddings. To address this, we introduce FlowTok, a minimal framework that seamlessly flows across text and images by encoding images into a compact 1D token representation. Compared to prior methods, this design reduces the latent space size by  $3.3\times$  at an image resolution of 256, eliminating the need for complex conditioning mechanisms or noise scheduling. Moreover, FlowTok naturally extends to image-to-text generation under the same formulation. With its streamlined architecture centered around compact 1D tokens, FlowTok is highly memory-efficient, requires significantly fewer training resources, and achieves much faster sampling speeds—all while delivering performance comparable to state-of-the-art models. Code is available at <https://github.com/TACJu/FlowTok>.

Figure 2. **Text as Conditions vs. Direct Flow between Modalities.** *Top:* Conventional text-to-image generation relies on the diffusion process, where text serves as a conditioning signal to guide the denoising process. *Bottom:* The proposed FlowTok enables direct flow between text and image modalities by projecting both into a shared, compact 1D latent space, facilitating seamless generation of both.

## 1. Introduction

Bridging different modalities is essential for comprehending the diverse forms of data that represent our world, encompassing both understanding and generation. In multimodal understanding, extensive research has focused on designing architectures that project different modalities into a shared latent space [4, 18, 22, 32, 36, 37, 45, 46, 55, 65, 85]. These approaches have significantly advanced cross-modal representation learning and real-world understanding by leveraging a common latent space between modalities.

In contrast, multimodal generation (*e.g.*, text-to-image generation) follows a different paradigm, primarily relying on the diffusion process [35, 52, 61, 75, 76], where the source modality (*e.g.*, text) serves as a conditioning signal to guide the denoising process. Various conditioning mechanisms have been explored, including concatenation [9], cross-attention [14, 70], conditioning embeddings [61], and hybrid strategies [24, 39]. While effective, these approaches introduce substantial complexity, requiring intricate conditioning mechanisms and noise scheduling. This naturally raises an important question: *Can we unify multimodal understanding and generation by enabling direct transitions within a shared latent space?*

To address this question, we revisit flow matching [5, 49, 54]—a modern generative framework that learns a direct path from noise to data, enabling faster convergence and accelerated sampling, leading to state-of-the-art multimodal generation results [24, 41]. Unlike diffusion models, flow matching is not constrained to using noise as the

source distribution; instead, it only requires the source and target distributions to share the same shape. Pioneering works [5, 50, 73, 82, 96] have demonstrated its effectiveness in learning direct mappings within the same modality (*e.g.*, image-to-image generation). Meanwhile, CrossFlow [51] extends flow matching to cross-modal learning by mapping text into a 2D latent space to match the shape of image embeddings, paving the way for new possibilities. However, while this approach simplifies the overall pipeline, it still operates on 2D latent representations. As a result, the additional computational overhead introduced by the text variational autoencoder [40] in CrossFlow makes it slower than modern text-to-image diffusion models like SD1.5 and SD2.1 [70], ultimately contradicting its original goal of efficiency.

To this end, we introduce FlowTok, a minimal framework that enables seamless **Flowing of Tokens** across text and image—the two most prevalent modalities (Fig. 2). At the core of FlowTok, both text and images are encoded into compact 1D latent tokens within a unified space, enabling direct flow matching between them. On the text side, FlowTok employs a pre-trained text encoder [65] to extract initial 1D text embeddings. Since these embeddings typically reside in a higher-dimensional space than image latents, FlowTok introduces a lightweight text projector to map text embeddings into a low-dimensional variational latent space. On the image side, FlowTok builds on recent advancements in image tokenization [39, 93] to encode images into compact 1D latent tokens. Specifically, we enhance TA-TiTok [39] by integrating RoPE [78] and SwiGLU FFN [72], improving positional information handling and reconstruction quality.

To enable direct flow matching, we align the number of image latent tokens  $K$  in TA-TiTok to match the text encoder’s output sequence length ( $K = 77$  for CLIP text encoder).

By integrating these simple yet effective designs across text and image modalities, FlowTok represents both in the same 1D low-dimensional space with shape  $77 \times 16$  (77 tokens, each with 16 dimensions). This compact representation is  $3.3\times$  smaller than typical 2D flow matching shapes [77] of  $32 \times 32 \times 4$  for image resolutions of 256. This alignment enables fast, direct flow matching and seamless evolution between the two modalities.

Unlike standard flow matching models [49, 54, 57], FlowTok eliminates the need for intricate conditioning mechanisms, offering a fully self-attention-based generative model. This allows for direct flow across modalities without additional complexity. Unlike CrossFlow [51], which converts text into 2D embeddings, FlowTok retains the 1D structure of text embeddings, avoiding the need for flattening and transformation into 2D. This simplifies the framework while eliminating reliance on heavy parametric contrastive losses for semantic preservation.

As a result, FlowTok offers a streamlined and resource-efficient training process. Its largest variant, FlowTok-H (1.1B), supports a batch size of 8K on 8 A100 GPUs without requiring gradient checkpointing or gradient accumulation. In contrast, recent text-to-image models of similar scale typically require 32 to 64 A100 GPUs to train with a batch size of only 2K [14, 70]. Moreover, FlowTok converges significantly faster, as shown in Fig. 3a, with FlowTok-H completing training in just 26.1 8-A100 days—far less than SD 2.1 [70], which requires 1041.6 8-A100 GPU days.

Inference is also highly efficient, with FlowTok achieving over  $10\times$  the throughput of Show-o [87] and CrossFlow [51], as shown in Fig. 3b. This dramatically reduces computational costs, making text-to-image research far more accessible. To ensure full reproducibility, we train FlowTok exclusively on publicly available datasets, avoiding reliance on high-quality proprietary data. Remarkably, despite its minimalist design and reduced data requirements, FlowTok achieves state-of-the-art text-to-image performance.

Beyond text-to-image generation, FlowTok seamlessly extends to image-to-text generation, maintaining strong performance under the same minimalist framework. We believe our work establishes a strong foundation for future research in generalized cross-modality generation.

## 2. Related Work

**Flow Matching.** Flow matching [5, 49, 54] models generative processes by constructing a transport map between two distributions via an ordinary differential equation (ODE). It has recently gained traction as the foundation for state-of-the-art text-to-image and text-to-video synthesis models [16, 24, 63, 67, 69], offering faster training and sampling

Figure 3. **COCO Results.** FlowTok presents comparable performance to previous methods on COCO while significantly reducing training resource requirements (Fig. 3a) and achieving much faster sampling speed (Fig. 3b). This efficiency stems from its minimalist design centered around 1D tokens, which facilitates direct transformation between text and image modalities, leading to superior performance with enhanced computational efficiency. We note that the compared CrossFlow [51] uses high-quality proprietary data.

compared to conventional diffusion methods [35, 52, 53, 61]. Several works further optimize flow trajectories by minimizing curvature [43, 64, 81]. Despite its theoretical flexibility in handling arbitrary distributions, recent approaches primarily evolve noise into target distributions, often relying on complex control signal conditioning, which complicates the pipeline and overlooks the potential of directly transforming control signals into target distributions. In contrast, only a few works [5, 50, 54, 73, 82, 96] explore direct transport within the same modality (e.g., image-to-image [26, 54, 96]), leaving cross-modal transport (e.g., text-to-image) underexplored. In this work, we introduce FlowTok, a minimal yet effective framework that enables seamless flow across text and image modalities using 1D tokens. Unlike CrossFlow [51], which follows a similar paradigm but relies on 2D latent representations and incurs additional computational costs due to the text variational encoder, FlowTok operates within a unified, compact 1D token space. This design achieves a  $3.3\times$  compression rate in latent size, significantly reducing training costs and accelerating the sampling process, all while maintaining state-of-the-art performance.

**Text-to-Image Generation.** Text-to-image generation has advanced rapidly in recent years, driven by various generative paradigms, including diffusion models [14, 62, 70, 71], flow matching models [16, 24, 74, 88, 94], sequence models [25, 28, 68, 91, 92], and masked generative models [7, 11, 39, 86]. While early works in each category establish the foundation for their respective approaches, subsequent advancements across different model types have primarily emerged from three key areas: careful data collection and advanced image recaptioning for improved data quality [10, 20, 39], architectural and conditioning improvements for faster convergence and better text-image align-

ment [14, 16, 24, 25], and micro-conditioning for finer control over generated samples [7, 39, 62]. By contrast, this work introduces a minimalist framework FlowTok that directly maps text tokens to image tokens, eliminating the need for noise scheduling and complex conditioning mechanisms. This streamlined design enhances both efficiency and simplicity while maintaining competitive performance.

### 3. Preliminary

**1D Visual Tokenization** [39, 93] deviates from traditional 2D grid-based latent tokenization by adopting a compact 1D representation, eliminating the need to preserve the 2D spatial structure. This work focuses on continuous 1D visual tokens for flow matching. During tokenization, given an input image  $\mathbf{I} \in \mathbb{R}^{H \times W \times 3}$ , the image is downsampled by a factor of  $f$ , resulting in patches  $\mathbf{P} \in \mathbb{R}^{\frac{H}{f} \times \frac{W}{f} \times D}$ . These patches are concatenated with a set of latent tokens  $\mathbf{L} \in \mathbb{R}^{K \times D}$  to form a sequence that is passed through a Vision Transformer (ViT) [21] encoder,  $Enc$ , to generate embeddings. Only the embeddings corresponding to the latent tokens are retained, forming a compact 1D latent representation. This representation is modeled as a Gaussian distribution with KL divergence regularization, resulting in a compact 1D VAE representation,  $\mathbf{Z}_I \in \mathbb{R}^{K \times D}$ . In the de-tokenization phase, text guidance is applied by incorporating text embeddings generated by a pre-trained text encoder [65]. These text embeddings are projected through a linear layer to align with the channel dimensions of ViT decoder, resulting in  $\mathbf{T} \in \mathbb{R}^{N \times D}$ , where  $N$  is the number of context tokens predefined by the text encoder. The text embedding  $\mathbf{T}$  is then concatenated with the latent tokens  $\mathbf{Z}_I$  and a set of mask tokens  $\mathbf{M} \in \mathbb{R}^{\frac{H}{f} \times \frac{W}{f} \times D}$ . The combined sequence is passed through the decoder  $Dec$ , yielding the reconstructed image  $\hat{\mathbf{I}}$ . Formally, with  $\oplus$  denoting concatenation, the tokenization and de-tokenization can be represented as:

$$\begin{aligned} \mathbf{Z}_I &= Enc(\mathbf{P} \oplus \mathbf{L}), \\ \hat{\mathbf{I}} &= Dec(\mathbf{Z}_I \oplus \mathbf{T} \oplus \mathbf{M}). \end{aligned}$$

**Flow matching** [49, 54] is a framework that learns a continuous transformation between a source distribution and a target distribution. The source distribution is not necessarily required to be Gaussian noise, though we use Gaussian noise as a concrete example below.

During training, given a sample  $X$  from the target distribution, a sampled time step  $t \in [0, 1]$ , and a noise sample  $N \sim \mathcal{N}(0, I)$  from the source distribution. An intermediate representation  $X_t$  is obtained by:

$$X_t = (1 - t) \cdot X + t \cdot N.$$

The flow matching model is trained to estimate the velocity field  $V_t$ , which describes the direction from the source

to the target distribution. Taking the derivative of  $X_t$  with respect to  $t$ , we have:

$$V_t = \frac{dX_t}{dt} = N - X,$$

where  $V_t$  indicates the direction from the source to the target distribution such that the induced flow accurately transports the source distribution to the target distribution.

Notably, while the source distribution is typically modeled as Gaussian noise in generative frameworks [24], the flow matching formulation generalizes to arbitrary source distributions, provided that the source and target distributions share the same shape. In FlowTok, we directly define a unified latent space for image and text modalities, treating them as both source and target distributions. This design enables seamless generation across different modalities.

## 4. Method

In this section, we focus on text-to-image generation as the primary task to illustrate FlowTok. We first detail how images and text are projected into a unified, compact latent space as 1D tokens while preserving semantic information (Sec. 4.1). Next, we introduce FlowTok as a general framework for seamless flow between text and image tokens and discuss its extension to image-to-text generation under the same formulation (Sec. 4.2).

### 4.1. Unifying Latent Space of Image and Text

The structural discrepancy between text and images presents a significant challenge in unifying them within the same latent space for flow matching. Text is inherently semantic, encoded as a 1D latent sequence with high-dimensional channels to preserve meaning, whereas images contain spatially redundant information and are typically represented as 2D feature maps with lower channel dimensions to retain spatial priors. To bridge this gap, we propose encoding images into compact 1D tokens by leveraging recent advancements in image tokenization. This formulation helps preserve the 1D structure of text embeddings, requiring only their projection into a more compressed set of tokens while ensuring that semantic information is retained. Below, we detail how both images and text are encoded.

**Encoding Images into Compact Tokens.** We build upon the core idea of TA-TiTok [39] with several enhancements to improve our image tokenizer. Specifically, we replace the original learnable 1D positional embedding with RoPE [78] to enhance TA-TiTok performance. Additionally, we substitute the MLP blocks in the Vision Transformer (ViT) [21] with SwiGLU FFN [72], which helps learn a more effective latent space [15, 90]. To align with the number of context tokens  $N$  of the text encoder, we set the number of latent tokens  $K$  in TA-TiTok accordingly ( $K = N = 77$  for

Figure 4. **Overview of FlowTok.** FlowTok is a minimal framework that facilitates seamless flow between 1D **text tokens** and **image tokens** for both text-to-image and image-to-text generation. *Top:* For text-to-image generation, the input text is encoded by the CLIP text encoder into  $\mathbf{T}_{\text{init}} \in \mathbb{R}^{N \times C}$ , projected into a low-dimensional latent space as text tokens  $\mathbf{Z}_{\text{T}} \in \mathbb{R}^{N \times D}$ , then transformed into image tokens  $\mathbf{Z}_{\text{I}} \in \mathbb{R}^{N \times D}$  of the same shape through flow matching and decoded by a 1D Image VAE Decoder to generate the final image. *Bottom:* For image-to-text generation, an input image is encoded by a 1D Image VAE Encoder into  $\mathbf{Z}_{\text{I}}$ , mapped to  $\mathbf{Z}_{\text{T}}$  through flow matching and decoded into text via a text decoder. Unlike conventional approaches that rely on 2D noise and image latents (e.g.,  $32 \times 32 \times 4$  for 256-resolution images) with text as conditions, our direct 1D transformation (i.e.,  $77 \times 16$ ) achieves a  $3.3\times$  compression rate, significantly reducing memory costs, accelerating training, and enabling faster inference.

CLIP [65]). As a result, the encoder of TA-TiTOK encodes each image into a compact 1D token sequence  $\mathbf{Z}_{\text{I}} \in \mathbb{R}^{K \times D}$ .

**Transforming Texts into Compact Tokens.** We use a pre-trained text encoder [65] to extract the initial text embedding  $\mathbf{T}_{\text{init}} \in \mathbb{R}^{N \times C}$ , where  $C$  denotes the number of channels. Notably,  $C$  is typically much larger than the image latent size  $D$ , as it carries richer semantic information. Since our goal is to directly flow the text embedding into the image latent space, we need to ensure both embeddings have the same shape. While we already align  $K$  with  $N$  through careful tuning of the image tokenizer, ensuring the image is encoded to match the length of the text tokens. The remaining challenge lies in aligning the number of channels (i.e.,  $C$  and  $D$ ), which we resolve using a text projector. Since only the number of channels in  $\mathbf{T}_{\text{init}}$  needs adjustment while preserving its 1D shape, we employ a few simple Transformer blocks as the projector. To introduce variability in image generation from the same text, we model the projected text latents  $\mathbf{Z}_{\text{T}} \in \mathbb{R}^{N \times D}$  as a Gaussian distribution by applying KL divergence regularization  $\mathcal{L}_{\text{kld}}$ .

A crucial aspect of text-to-image generation is ensuring that the generated image accurately reflects the input text description. Since reducing the channel dimensions of text embeddings via a learnable projector may result in semantic information loss, we introduce an auxiliary text alignment loss  $\mathcal{L}_{\text{align}}$  to preserve semantic consistency. Specifically, we employ a lightweight MLP to project  $\mathbf{T}_{\text{init}}$  into a new space  $\mathbf{T}_{\text{P}} \in \mathbb{R}^{N \times D}$  for alignment. We then flatten and normalize both  $\mathbf{T}_{\text{P}}$  and  $\mathbf{Z}_{\text{T}}$  along the channel dimension

and compute a contrastive loss between them, inspired by CLIP [65]. Concretely, we calculate the scaled pairwise cosine similarities using a learnable temperature parameter  $\tau$ , followed by a symmetric cross-entropy loss:

$$\text{logits}_{\text{TZ}} = \exp(\tau) \times (\mathbf{T}_{\text{P}} \times \mathbf{Z}_{\text{T}}^{\top}),$$

$$\text{logits}_{\text{ZT}} = \exp(\tau) \times (\mathbf{Z}_{\text{T}} \times \mathbf{T}_{\text{P}}^{\top}),$$

$$\mathcal{L}_{\text{align}} = (\text{CE}(\text{logits}_{\text{TZ}}, \text{labels}) + \text{CE}(\text{logits}_{\text{ZT}}, \text{labels}))/2,$$

where  $\top$  denotes the transpose operation, CE represents the cross-entropy loss, and labels are assigned based on their batch indices, ensuring that each text token is explicitly trained to align with its corresponding CLIP text embedding within the same batch. We also explore alternative approaches to preserving semantic information, such as aligning with the average-pooled text embedding or using a cosine similarity loss with a margin. However, we find that the CLIP-style loss achieves the best performance. More details are provided in Sec. 5.3.

Through the aforementioned designs, FlowTok efficiently tokenizes text into the same low-dimensional latent space while preserving semantic information. This alignment with the tokenized image latent space establishes a foundation for direct flow between compressed text tokens  $\mathbf{Z}_{\text{T}}$  and image tokens  $\mathbf{Z}_{\text{I}}$ . Notably, when using CLIP as the text encoder, FlowTok effectively reduces the latent size compared to traditional 2D flow matching methods. At an image resolution of 256, the latent size is reduced from  $32 \times 32 \times 4$  to  $77 \times 16$ , achieving a  $3.3\times$  compression. This reduction significantly lowers memory requirements and accelerates training, en-

model	depth	width	mlp	heads	#params
FlowTok-B	12	768	3072	12	153M
FlowTok-XL	28	1152	4608	16	698M

Table 1. **Architecture Configuration of FlowTok.** Following prior work, we scale up DiT blocks across three configurations.

hancing the framework’s efficiency and scalability.

## 4.2. FlowTok: A General Framework for Seamless Flow Across Text and Image Tokens

**Text-to-Image Generation.** As shown in Fig. 4 (*top*), with both image and text mapped into the same latent space, FlowTok leverages vanilla flow matching [49] by stacking DiT blocks [61]. Notably, source modality (*i.e.*, text) is directly treated as the source distribution for flow matching, removing the need for concatenation or cross-attention within the DiT blocks. This design choice further simplifies the overall framework and streamlines text-to-image generation. Combined with the compact 1D tokens introduced in Sec. 4.1, FlowTok achieves high memory efficiency, supporting a batch size of 8K on 8 A100 GPUs. Additionally, it enables fast sampling, running over  $10\times$  faster than modern text-to-image diffusion models [70], significantly lowering the computational barrier for training large-scale text-to-image generative models.

**Image-to-Text Generation.** FlowTok can also be seamlessly extended to image-to-text generation using compact 1D image and text tokens under the same formulation, as shown in Fig. 4 (*bottom*). Specifically, the image tokens  $\mathbf{Z}_I$  flow to text tokens  $\mathbf{Z}_T$ , where a trained text decoder takes  $\mathbf{Z}_T$  as input and outputs tokenizer indices, which can then be decoded back into the corresponding caption.

## 5. Experimental Results

In this section, we first provide the implementation details of FlowTok (Sec. 5.1), followed by the main results on text-to-image and image-to-text generation (Sec. 5.2). Finally, we present the ablation studies to better understand the design choices of FlowTok in text-to-image generation (Sec. 5.3).

### 5.1. Implementation Details

**Image Tokenizer.** We build our image tokenizer upon the official TA-TiTOK [39] codebase with minimal modifications. The encoder uses ViT-B [21], while the decoder uses ViT-L, both operating with a patch size of  $f = 16$ . To align with the output sequence length of CLIP’s text encoder, we set the number of 1D latent tokens  $K$  to 77 and the token dimension to 16. Additionally, we enhance the tokenizer with RoPE [78] and SwiGLU FFN [72]. Notably, our enhanced tokenizer achieves a FID of 1.02 in a zero-shot evaluation

on the ImageNet validation set, matching the performance of the original TA-TiTOK with 128 tokens.

**Text Projector.** We train a text projector for text-to-image generation, which transforms CLIP text embeddings into a latent representation  $Z_T$  of shape  $77 \times 16$ , aligning with the image latent space  $Z_I$  encoded by our image tokenizer. The text projector consists of six Transformer [83] blocks, each comprising a multi-head self-attention mechanism and a multi-layer perceptron (MLP), both enhanced with skip connections [33] to ensure stable training.

**Text Decoder.** We train a text decoder for image-to-text generation, composed of six Transformer [83] blocks, similar to the text projector. The decoder takes the text latent representation  $Z_T$  as input and outputs the corresponding CLIP text tokenizer indices, which can be further converted into text using the CLIP text tokenizer.

**FlowTok.** We adopt DiT [61] blocks as the fundamental building units of our FlowTok to model token interactions. Specifically, we follow the DiT architecture to implement FlowTok-B for efficient ablation studies and FlowTok-XL for enhanced performance. To further push the performance, we scale up the depth, width, and number of attention heads, constructing FlowTok-H with 1.1B parameters. The detailed model configurations are provided in Tab. 1.

**Dataset.** We employ open-source datasets [39] to facilitate the reproducibility of FlowTok’s simple framework. Specifically, our image tokenizer is trained on DataComp-1B [27], and our text tokenizer is trained on COCO [48]. For text-to-image generation, inspired by recent works [13, 14, 19, 95], we adopt a two-stage training strategy: pre-training and fine-tuning. The pre-training stage leverages a combination of DataComp-1B [27], CC12M [12], and LAION-aesthetic [1], while the fine-tuning stage incorporates additional high-quality datasets, including LAION-art [2], LAION-pop [3], JourneyDB [79], and DALLE3-1M [23]. For image-to-text generation, we follow the Karpathy split [38] of COCO [17] to divide the training and validation sets. Detailed dataset information is provided in the Appendix.

**Training.** The training objectives of FlowTok primarily focus on predicting velocity in flow matching, denoted as  $\mathcal{L}_{fm}$ . For text-to-image generation, we introduce two additional losses: KL-divergence loss ( $\mathcal{L}_{kld}$ ) to enforce a Gaussian distribution on text tokens and text alignment loss ( $\mathcal{L}_{align}$ ) to preserve semantic information as discussed in Sec. 4.1. Formally, the overall training objective is:

$$\mathcal{L} = \mathcal{L}_{fm} + \gamma_1 * \mathcal{L}_{kld} + \gamma_2 * \mathcal{L}_{align},$$

where  $\gamma_1$  and  $\gamma_2$  control the weighting of losses. By default, we set  $\gamma_1$  to  $1 \times 10^{-4}$  and  $\gamma_2$  to 1 for text-to-image generation, while both are set to 0 for image-to-text generation.

**Evaluation.** We follow standard evaluation practices to report relevant metrics for both text-to-image and image-to-text generation. Specifically, for text-to-image genera-

SCD-Net [56]	37.3	28.1	58.0	118.0	21.6

Table 3. **Image-to-Text Generation Results on COCO.** FlowTok achieves performance comparable to state-of-the-art methods on image-to-text generation, evaluated on the COCO Karpathy split. For a fair comparison, we restrict our evaluation to non-autoregressive methods trained without CIDEr optimization.

tion, we report FID-30K on the COCO [48], and FID on MJHQ-30K [44]. For image-to-text generation, we report BLEU-4 [60], METEOR [8], ROUGE [47], CIDEr [84], and SPICE [6] on the COCO Karpathy Split [38]. To incorporate classifier-free guidance (CFG) [34] within FlowTok, we follow CrossFlow[51] and utilize a CFG indicator. Unless otherwise stated, we find that using only 20 steps for sampling is sufficient due to the small 1D latent shape of FlowTok. This significantly speeds up the inference process, enabling faster generation without compromising performance.

## 5.2. Main Results

**Text-to-Image Generation.** We report zero-shot text-to-image generation results on COCO [48] and MJHQ-30K [44] in Tab. 2. The compared methods are categorized

into two groups: *text as conditions*, where text serves as a guiding signal for image generation, and *text as source distributions*, where text is directly modeled as a distribution in the generative process. As observed, FlowTok achieves comparable performance to prior methods in both categories on COCO FID-30K. Specifically, compared to CrossFlow [51], which also uses text as the source distribution, FlowTok-H attains a FID-30K of 9.67—roughly on par with CrossFlow. When further evaluating FlowTok on MJHQ-30K to assess the aesthetic quality of generated images, we find that, despite being trained solely on publicly available datasets without access to high-quality proprietary data, FlowTok-XL already surpasses other state-of-the-art models, demonstrating its ability to generate diverse, high-quality images. Furthermore, FlowTok-H further improves the FID score to 7.15, underscoring its superior image generation capabilities.

Beyond performance, FlowTok requires significantly fewer training resources compared to existing state-of-the-art models. Specifically, FlowTok-XL completes training in just 20.4 8-A100 days, while FlowTok-H increases the budget slightly to 26.1 8-A100 days. In contrast, the most efficient text-as-condition model, PixArt- $\alpha$  [14], still demands 94.1 8-A100 days. Compared to CrossFlow [51], which also treats text as source distributions and requires 78.8 8-A100 days, FlowTok is much more efficient.

Additionally, FlowTok demonstrates significantly faster inference speeds. At 256px resolution, FlowTok-XL generates 22.7 images per second, while FlowTok-H achieves 18.2 images per second. In contrast, PixArt- $\alpha$  runs at 7.9 images per second, and Show-o at just 1.0 images per second. More notably, within the *text as source distributions* category, FlowTok achieves a 20 $\times$  speedup in sampling time

target	COCO FID-30K↓	loss type	COCO FID-30K↓	$\gamma_2$	COCO FID-30K↓
Ave Pool	36.02	Cosine	31.80	1.0	29.14
MLP	29.14	Contrastive	29.14	2.0	30.59

(a) Text Alignment Target

(b) Text Alignment Loss Function

(c) Text Alignment Loss Weight

Table 4. **Ablation Studies on Text Alignment Loss.** We conduct comprehensive ablation studies on three key aspects of the text alignment loss  $\mathcal{L}_{\text{align}}$ : the alignment target (Tab. 4a), the choice of loss function (Tab. 4b), and the loss weight  $\gamma_2$  (Tab. 4c), aiming to identify the most effective strategy for preserving semantic information within FlowTok during text-to-image generation. For efficient verification, we report FID-30K on COCO using FlowTok-B, without applying the CFG indicator.

compared to CrossFlow, which runs at only 1.1 images per second. This efficiency stems from FlowTok’s streamlined framework and its effective use of 1D tokens, significantly reducing computational overhead.

**Image-to-Text Generation.** We evaluate image-to-text generation on COCO [48] using the Karpathy split [38], with results summarized in Tab. 3. To ensure a fair comparison, we categorize methods into two groups: *direct flow from image to text distributions*, which represents a new paradigm leveraging flow matching for direct image-to-text transformation, and *other methods*, considering only those trained without CIDEr optimization. Within the direct flow category, FlowTok-XL consistently outperforms its counterpart, CrossFlow [51], across most metrics. Specifically, FlowTok-XL achieves a BLEU-4 (B@4) score of 37.1, surpassing CrossFlow by 0.7, and a CIDEr score of 117.0, exceeding CrossFlow by 0.8. Moreover, compared to state-of-the-art methods from other paradigms, FlowTok-XL demonstrates competitive performance, highlighting direct flow matching as a promising approach for image-to-text generation. Notably, FlowTok performs image-to-text generation under the same formulation using compact 1D tokens, theoretically requiring fewer training resources and enabling faster sampling compared to paradigms that operate on 2D latents, as adopted by CrossFlow. However, a direct quantitative comparison is not possible, as CrossFlow has not released the corresponding checkpoint for evaluation.

### 5.3. Ablation Studies

We conduct ablation studies on text-to-image generation using FlowTok-B and evaluate them on COCO for efficiency. Our ablations focus on the design of the text alignment loss, as it plays a critical role in preserving semantic information. Specifically, we investigate three key aspects: the text alignment target (Tab. 4a), the choice of loss function (Tab. 4b), and the loss weight (Tab. 4c). Details are provided below.

**Text Alignment Target.** We first investigate the choice of alignment target for the projected text tokens  $\mathbf{Z}_T$  in Tab. 4a. A straightforward baseline is to directly apply average pooling (row 1) to the original CLIP text embedding  $\mathbf{T}_{\text{init}}$  along the channel dimension, reducing the dimensionality from 768 to 16 to match  $\mathbf{Z}_T$ . However, this approach performs significantly worse compared to using a simple MLP to

learn the alignment target (row 2), as inspired by prior works [30, 59, 94]. We attribute this performance gap to the fact that adjacent channels in the CLIP text embedding are not necessarily correlated, and simple average pooling discards too much semantic information. In contrast, a learnable MLP mitigates this information loss, making it a more effective choice for defining the text alignment target.

**Text Alignment Loss Function.** Next, we examine the text alignment loss function in Tab. 4b. Besides the contrastive loss adopted from [65], we explore using a cosine similarity loss, similar to [89]. Specifically, we compute the cosine similarity between the text tokens and the alignment target, applying a penalty to pairs with similarity below a threshold. Our experiments show that while both loss functions are effective, the contrastive loss achieves better performance.

**Text Alignment Loss Weight.** Finally, we investigate the impact of the text alignment loss weight,  $\gamma_2$  in Tab. 4c. Our results indicate that setting  $\gamma_2$  to 1.0, equal to the weight of the flow matching loss, is sufficient to preserve semantic information while maintaining high-quality image generation. Increasing  $\gamma_2$  further can cause the text alignment loss to dominate the overall objective during early training stages, potentially hindering final performance.

## 6. Conclusion

In this paper, we introduce FlowTok, a minimal yet powerful framework that enables seamless direct flow between 1D text and image tokens. Through carefully designed key modules and loss functions, FlowTok projects both modalities into a unified 1D latent space while preserving semantic information, enabling both text-to-image and image-to-text generation under the same formulation. This design makes FlowTok highly memory-efficient, supporting an 8K batch size on just 8 A100 GPUs during training. Additionally, its simplicity accelerates convergence—within approximately 20 days on 8 A100 GPUs, FlowTok achieves performance comparable to state-of-the-art models that require significantly longer training times. The streamlined design also enables over  $10\times$  faster sampling than modern text-to-image generative models. By releasing our code, we aim to further advance research in text-image cross-modal generation.
